

PerlGuts Illustrated

Version 0.49, for perl 5.20 and older

This document is meant to supplement the *perlguts(1)* manual page that comes with Perl. It contains commented illustrations of all major internal Perl data structures. Having this document handy hopefully makes reading the Perl source code easier. It might also help you interpret the *Devel::Peek* dumps.

Most of the internal perl structures had been refactored twice, with 5.10 and 5.14. The comparison links and illustrations for 5.8 - 5.20 are now included in this single document, but also available as extra files. 5.10 to 5.12 changes: only *OOK*.

- [illguts for 5.8 and older](#)
- [illguts for 5.10](#)
- [illguts for 5.12](#)
- [illguts for 5.14 - 5.18](#)
- [illguts since 5.18](#)

The first things to look at are the data structures that represent Perl data; scalars of various kinds, arrays and hashes. Internally Perl calls a scalar *SV* (scalar value), an array *AV* (array value) and a hash *HV* (hash value). In addition it uses *IV* for integer value, *NV* for numeric value (aka double), *PV* for a pointer value (aka string value (char*), but 'S' was already taken), and *RV* for reference value. The *IVs* are further guaranteed to be big enough to hold a `void*` pointer.

The internal relationship between the Perl data types is really object oriented. Perl relies on using C's structural equivalence to help emulate something like C++ inheritance of types. The various data types that Perl implement are illustrated in this class hierarchy diagram. The arrows indicate inheritance (IS-A relationships).

Until 5.8:

Since 5.14:

As you can see, Perl uses multiple inheritance with *SvNULL* (also named just *SV*) acting as some kind of virtual base class. All the Perl types are identified by small numbers, and the internal Perl code often gets away with testing the ISA-relationship between types with the `<=` operator. As you can see from the figure above, this can only work reliably for some comparisons. All Perl data value objects are tagged with their type, so you can always ask an object what its type is and act according to this information.

The symbolic **SvTYPE** names (and associated value) are with 5.14:

svtype	5.20	5.14 - 5.18	5.10	5.6 + 5.8
0	SVt_NULL	SVt_NULL	SVt_NULL	SVt_NULL
1	SVt_IV	SVt_BIND	SVt_BIND	SVt_IV
2	SVt_NV	SVt_IV	SVt_IV	SVt_NV
3	SVt_PV	SVt_NV	SVt_NV	SVt_RV
4	SVt_INVLIST	SVt_PV	SVt_RV	SVt_PV
5	SVt_PVIV	SVt_PVIV	SVt_PV	SVt_PVIV
6	SVt_PVNV	SVt_PVNV	SVt_PVIV	SVt_PVNV
7	SVt_PVMG	SVt_PVMG	SVt_PVNV	SVt_PVMG
8	SVt_REGEXP	SVt_REGEXP	SVt_PVMG	SVt_PVBM
9	SVt_PVGV	SVt_PVGV	SVt_PVGV	SVt_PVLV
10	SVt_PVLV	SVt_PVLV	SVt_PVLV	SVt_PVAV
11	SVt_PVAV	SVt_PVAV	SVt_PVAV	SVt_PVHV
12	SVt_PVHV	SVt_PVHV	SVt_PVHV	SVt_PVCV
13	SVt_PVCV	SVt_PVCV	SVt_PVCV	SVt_PGV
14	SVt_PVFM	SVt_PVFM	SVt_PVFM	SVt_PVFM
15	SVt_PVIO	SVt_PVIO	SVt_PVIO	SVt_PVIO

In addition to the simple type names already mentioned, the following names are found in the hierarchy figure: An *PVIV* value can hold a string and an integer value. An *PVNV* value can hold a string, an integer and a double value. The *PVMG* is used when magic is attached or the value is blessed. The *PVLV* represents a LValue object. *RV* is now a separate scalar of type *SVt_IV*. *CV* is a code value, which represents a perl

function/subroutine/closure or contains a pointer to an XSUB. *GV* is a glob value and *IO* contains pointers to open files and directories and various state information about these. The *PVFM* is used to hold information on forms. *P5RX* was formerly called *PVBM* for Boyer-Moore (match information), but contains now regex information. *BIND* was a unused placeholder for read-only aliases or VIEW. (#29544, #29642) *INVLIST* is an CORE internal inversion list object only, used for faster utf8 matching, since 5.19.2. Same layout as a PV.

A Perl data object can change type as the value is modified. The SV is said to be upgraded in this case. Type changes only go down the hierarchy. (See the `sv_upgrade()` function in `SV.c`.)

The actual layout in memory does not really match how a typical C++ compiler would implement a hierarchy like the one depicted above. Let's see how it is done.

*In the description below we use field names that match the macros that are used to access the corresponding field. For instance the `xpv_cur` field of the `xpvXX` structs are accessed with the `SvCUR()` macro. The field is referred to as **CUR** in the description below. This also match the field names reported by the `Devel::Peek` module.*

SV_HEAD and struct sv

The simplest type is the "struct sv". It represents the common structure for a SV, GV, CV, AV, HV, IO and P5RX, without any struct xpv<xx> attached to it. It consist of four words, the SV_HEAD with 3 values and the SV_U union with one pointer.

SV_HEAD and SV_U union

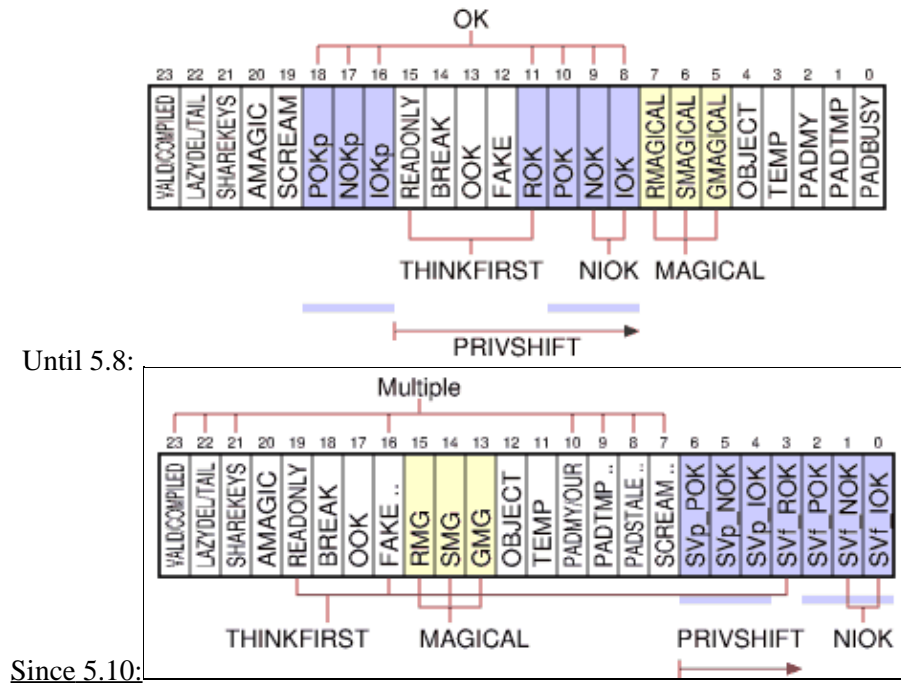

The first word contains the **ANY** pointer to the optional body. All types are implemented by attaching additional data to the ANY pointer, just the RV not.

The second word is an 32 bit unsigned integer reference counter (**REFCNT**) which should tell us how many pointers reference this object. When Perl data types are created this value is initialized to 1. The field must be incremented when a new pointer is made to point to it and decremented when the pointer is destroyed or assigned a different value. When the reference count reaches zero the object is freed.

The third word contains a **FLAGS** field and a **TYPE** field as 32 bit unsigned integer.

Since 5.10 the fourth and last HEAD word contains the **sv_u union**, which contains a pointer to another SV (a RV), the **IV** value, the **PV** string, the **AV** svu_array, a **HE** hash or a **GP** struct. The TYPE field contains a small number (0-127, mask **0xff**) that represents one of the **Svt** types shown in the type hierarchy figure above. The FLAGS field has room for 24 flag bits (**0x00000100-0x80000000**), which encode how various fields of the object should be interpreted, and other state information. Some flags are just used as optimizations in order to avoid having to dereference several levels of pointers just to find that the information is not there.

The purpose of the **SvFLAGS** bits are:

0x00000100 Svf_IOK (public integer)

This flag indicates that the object has a valid public IVX field value. It can only be set for value type SvIV or subtypes of it.

(Svf_IOK was 0x00010000 until 5.10)

0x00000200 Svf_NOK (public number)

This flag indicates that the object has a valid public NVX field value. It can only be set for value type SvNV or subtypes of it.

(Svf_NOK was 0x00020000 until 5.10)

0x00000400 Svf_POK (public string)

This flag indicates that the object has a valid public PVX, CUR and LEN field values (i.e. a valid string value). It can only be set for value type SvPV or subtypes of it.

(Svf_POK was 0x00040000 until 5.10)

0x00000800 Svf_ROK (valid reference pointer)

This flag indicates that the type should be treated as an SvRV and that the RV field contains a valid reference pointer.

(Svf_ROK was 0x00080000 until 5.10)

0x00001000 SvP_IOK (private integer)

This flag indicates that the object has a valid non-public IVX field value. It can only be set for value type SvIV or subtypes of it.

(SVp_IOK was 0x01000000 until 5.10)

The private OK flags (SVp_IOK, SVp_NOK, SVp_POK) are used by the magic system. During execution of a magic callback, the private flags will be used to set the public flags. When the callback returns, then the public flags are cleared. This effectively is used to pass the value to get/set to/from magic callbacks.

0x00002000 **SVp_NOK** (private number)

This flag indicates that the object has a valid non-public NVX field value, a double float. It can only be set for value type SvNV or subtypes of it.

(SVp_NOK was 0x02000000 until 5.10)

0x00004000 **SVp_POK** (private string)

This flag indicates that the object has a valid non-public PVX, CUR and LEN field values (i.e. a valid string value). It can only be set for value type SvPV or subtypes of it.

(SVp_POK was 0x04000000 until 5.10)

0x00008000 **SVp_SCREAM**

A string SvPV* type has been studied.

(SVp_SCREAM was 0x08000000 until 5.10)

0x00008000 **SVphv_CLONEABLE**

For PVHV (stashes only) to clone its objects.

(Introduced with 5.8.7)

0x00008000 **SVpgv_GP**

GV has a valid GP.

(Introduced with 5.10)

0x00008000 **SVprv_PCS_IMPORTED**

RV is a proxy for a constant subroutine in another package. Set the CvIMPORTED_CV_ON() if it needs to be expanded to a real GV.

(Introduced with 5.8.9)

0x00010000 **SVf_IsCOW**

copy on write or shared hash key if SvLEN == 0.

(Introduced with 5.18. This bit was used for SVs_PADSTALE, SVpad_STATE before)

0x00020000 **SVs_PADTMP**

in use as tmp

(SVs_PADTMP was 0x00000200 from 5.6-5.8)

0x00020000 **SVs_PADSTALE**

lexical has gone out of scope

(SVs_PADSTALE was 0x00010000 from 5.10-5.14)

0x00020000 **SVpad_TYPED**

pad name is a typed Lexical

(SVpad_TYPED was 0x40000000 in 5.8)

0x00040000 **SVs_PADMY**

in use a "my" variable

(SVs_PADMY was 0x00000400 in 5.6-5.8)

0x00040000 **SVpad_OUR**

pad name is "our" instead of "my"

(SVpad_OUR was 0x80000000 in 5.6-5.8)

0x00080000 **SVs_TEMP**

string is stealable

(SVs_TEMP was 0x00000800 in 5.6-5.8)

0x00100000 SVs_OBJECT

This flag is set when the object is "blessed". It can only be set for value type SvPVMG or subtypes of it. This flag also indicates that the STASH pointer is valid and points to a namespace HV.

(SVs_OBJECT was 0x00001000 in 5.6-5.8)

0x00200000 SVs_GMG (Get Magic)

This flag indicates that the object has a magic *get* or *len* method to be invoked. It can only be set for value type SvPVMG or subtypes of it. This flag also indicate that the MAGIC pointer is valid. Formerly called GMAGICAL.

(SVs_GMG was 0x00002000 in 5.6-5.8)

0x00400000 SVs_SMG (Set Magic)

This flag indicates that the object has a magic *set* method to be invoked. Formerly called SMAGICAL.

(SVs_SMG was 0x00004000 in 5.6-5.8)

0x00800000 SVs_RMG (Random Magic)

This flag indicates that the object has any other magical methods (besides get/len/set magic method) or even methodless magic attached.

(SVs_RMG was 0x00008000 in 5.6-5.8)

The SVs_RMG flag (formerly called RMAGICAL) is used mainly for tied HV and AV (having 'P' magic) and SVs which have magic *clear* method. It is used as an optimization to avoid setting SVs_GMG and SVs_SMG flags for SVs which need to be marked as MAGICAL otherwise.

Any of SVs_GMG, SVs_SMG and SVs_RMG is called MAGICAL.

0x01000000 SVf_FAKE

0: glob or lexical is just a copy

1: SV head arena wasn't malloc(ed)

2: in conjunction with SVf_READONLY marked a shared hash key scalar (SvLEN == 0) or a copy on write string (SvLEN != 0) until 5.18 which came with a separate SvIsCOW(sv)

3: For PVCV, whether CvUNIQUE(cv) refers to an eval or once only [CvEVAL(cv), CvSPECIAL(cv)]

4: On a pad name SV, that slot in the frame AV is a REFCNT'ed reference to a lexical from "outside"

(SVf_FAKE was 0x00100000 in 5.6-5.8)

0x01000000 SVphv_REHASH

5: On a PVHV, hash values are being recalculated

(SVphv_REHASH was 0x10000000 in 5.8)

0x02000000 SVf_OOK (Offset OK)

For a PVHV this means that a hv_aux struct is present after the main array.

This flag indicates that the string has an offset at the beginning. This flag can only be set for value type SvPVIV or subtypes of it. It also follows that the IOK (and IOKp) flag must be off when OOK is on. Take a look at the SvOOK figure below.

(SVf_OOK was 0x00200000 in 5.6-5.8)

0x04000000 SVf_BREAK

REFCNT is artificially low. Used by SVs in final arena cleanup. Set in S_regtry on PL_reg_curpm, so that perl_destruct() will skip it

- (SVf_BREAK was 0x00400000 in 5.6-5.8)*
0x08000000 **SVf_READONLY**
This flag indicates that the value of the object may not be modified. But it also used together with SVf_FAKE and SVf_ROK for other purposes.
(SVf_READONLY was 0x00800000 in 5.6-5.8)
- 0x10000000 **SVf_AMAGIC**
has magical overloaded methods
- 0x20000000 **SVphv_SHAREKEYS**
Only used by HVs when the keys live on a shared string table. See [HV](#) below.
- 0x20000000 **SVf_UTF8**
SvPV is UTF-8 encoded. This is also set on RVs whose overloaded stringification is UTF-8. This might only happen as a side effect of SvPV().
- 0x40000000 **SVpav_REAL**
Free old entries in AVs only. See description of [AV](#) below.
(Introduced with 5.10)
- 0x40000000 **SVphv_LAZYDEL**
Only used by HVs. This is only set true on a PVGV when it's playing "PVBM", but is tested for on any regular scalar (anything <= PVLV). See description of [HV](#) below.
- 0x40000000 **SVpbm_VALID**
Clashes with SVpad_NAME. See description of [PVBM](#) below.
(SVpbm_VALID was 0x80000000 in 5.6-5.8)
- 0x40000000 **SVrepl_EVAL**
Replacement part of s///e
- 0x80000000 **SVf_IVisUV**
Use XPVUV instead of XPVIV. For [IV](#)s only (IV, PVIV, PVNV, PVMG, PVGV and maybe PVLV).
- 0x80000000 **SVpav_REIFY**
Can become real. For [PVAV](#) only.
(Introduced with 5.10)
- 0x80000000 **SVphv_HASKFLAGS**
Keys have flag byte after hash. For [PVHV](#) only.
(Introduced with 5.8.0)
- 0x80000000 **SVpfm_COMPILED**
FORMLINE is compiled. For [PVFM](#) only.
- 0x80000000 **SVpbm_TAIL**
PVGv when SVpbm_VALID is true. Only used by SvPVBMs. See description of [PVBM](#) below.
(SVpbm_TAIL was 0x40000000 in 5.6-5.8)
- 0x80000000 **SVprv_WEAKREF**
RV upwards. However, SVf_ROK and SVp_IOK are exclusive. For [RV](#) only.
- 0x80000000 **SVpad_STATE**
pad name is a "state" var
(SVpad_STATE was 0x00010000 in 5.10-5.14)

The `struct sv` is common for all variable types in Perl. In the Perl source code this structure is typedefed to `SV`, `RV`, `AV`, `HV`, `CV`, `GV`, `IO` and `P5RX`. Routines that can take any type as parameter will have `SV*` as parameter. Routines that only work with arrays or hashes have `AV*` or `HV*` respectively in their parameter list. Likewise for the rest.

Arena

Since 5.10 SV heads and bodies are allocated in 4K arenas chunks. Heads need 4 fields, bodies are kept in unequally sized arena sets. Some types need no body (*NULL*, *IV*, *RV*), and some allocate only partial bodies with "ghost" fields.

PL_sv_arenaroot points to the first reserved SV arena head with some private arena data, a link to the next arena, some flags, number of frees slots.

PL_sv_root points to the chained list of free SV head slots. When this becomes empty a new arena is allocated.

PL_body_arenas is the head of the uneven sized linked-list of body arenas.

PL_body_roots[] contains pointers to the list of free SV bodies per svtype.

SvPV

A scalar that can hold a string value is called an *SvPV*. In addition to the *SV* struct of *SvNULL*, an *xpv* struct ("body") is allocated and it contains 3-4 fields. **svu_pv** was formerly called **PVX** and before 5.10 it was the first field of *xpv*. `svu_pv/PVX` is the pointer to an allocated char array. All old field names **must** be accessed through the old macros, which is called `SvPVX()`. **CUR** is an integer giving the current length of the string. **LEN** is an integer giving the length of the allocated string. The byte at `(PVX + CUR)` should always be `'\0'` in order to make sure that the string is NUL-terminated if passed to C library routines. This requires that **LEN** is always at least 1 larger than **CUR**.

PerlGuts Illustrated

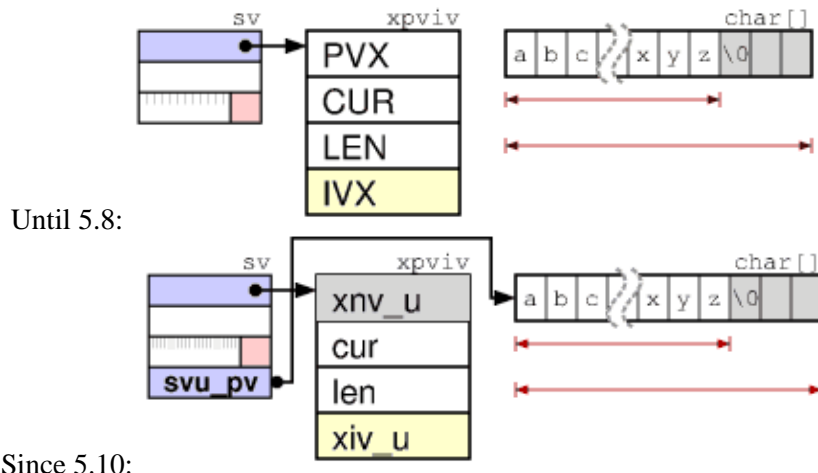

The **POK** flag indicates that the string pointed to by PVX contains a valid string value. If the POK flag is off and the ROK flag is turned on, then the PVX field is used as a pointer to an RV (see [SvRV](#) below) and the struct `xpv` is unused. An `SvPV` with both the POK and ROK flags turned off represents *undef*. The PVX pointer can also be NULL when POK is off and no string storage has been allocated.

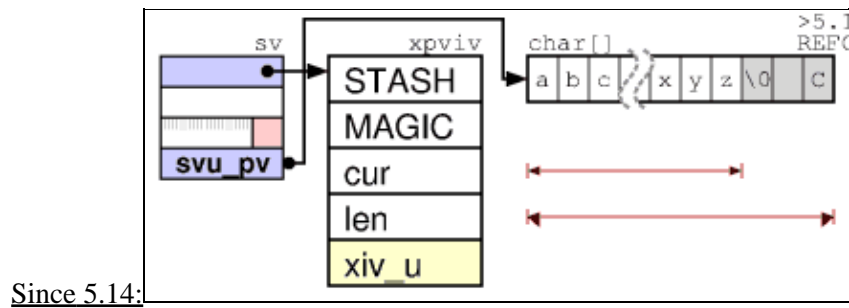

If the string is shared, created by `sharepvn`, the PVX is part of a **HEK**, i.e. the PVX points to the `hek_key` of the struct `hek`.

Since 5.18 there is now a separate **IsCOW** flag indicating that the PVX is shared as long as nobody is changing the value. The current implementation adds a **COW_REFCNT** byte at the aligned end of the PVX, which makes it unusable for COW in the static compiler and threads. It also requires that `LEN` is always at least 2 larger than `CUR` to keep the `\0` byte. But beware: shared COWs use `SvLEN=0` and set `hek_len`.

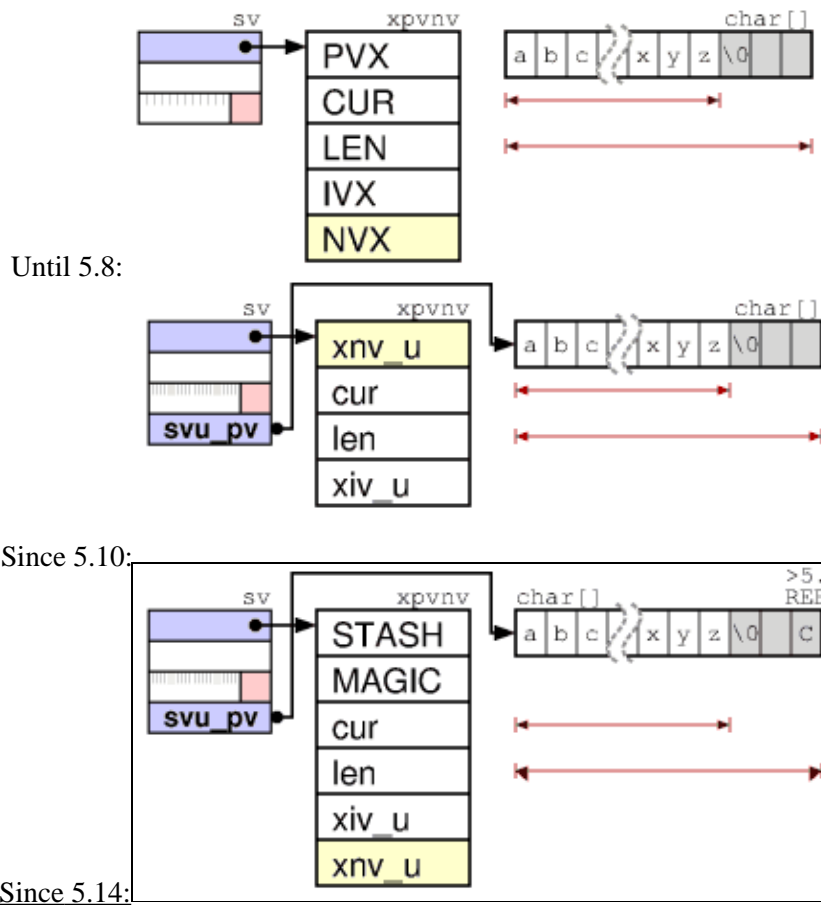

SvPVIV and SvPVNV

The `SvPVIV` type is like `SvPV` but has an additional field to hold a single integer value called **IVX** in `xiv_u`. The **IOK** flag indicates if the IVX value is valid. If both the IOK and POK flag is on, then the PVX will (usually) be a string representation of the same number found in IVX.

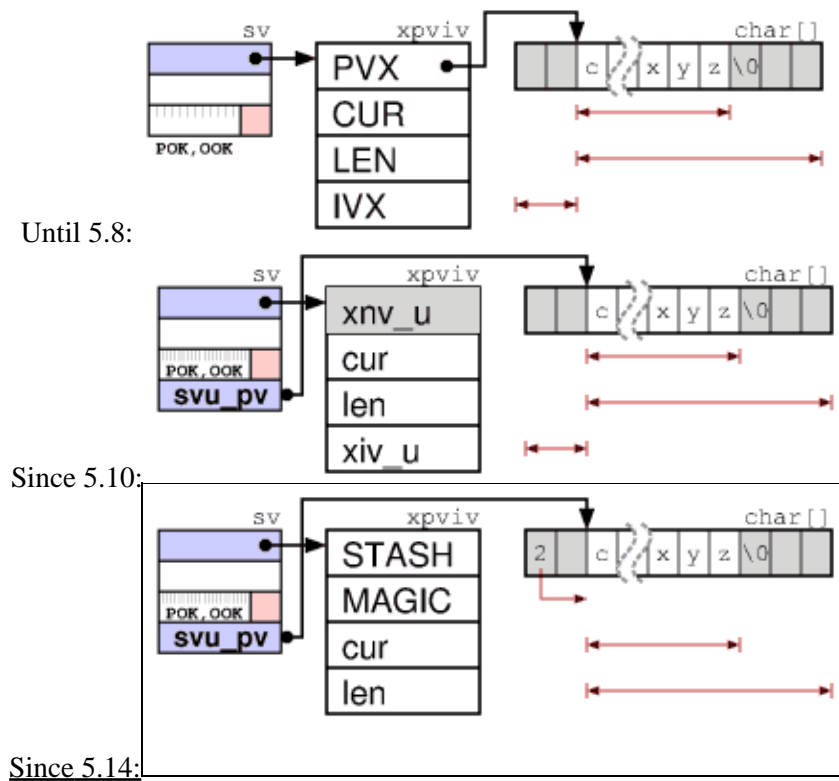

The *SvPVNV* type is like *SvPVIV* but uses the single *double* value called NVX in *xnv_u*. The corresponding flag is called NOK.

SvOOK

As a special hack, in order to improve the speed of removing characters from the beginning of a string, the *OOK flag* is used. *SvOOK_offset* used to be stored in *SvIVX*, but is since 5.12 stored within the first 8 bit (one char) of the buffer. The *PVX*, *CUR*, *LEN* is adjusted to point within the allocated string instead.

PerlGuts Illustrated

SvIV

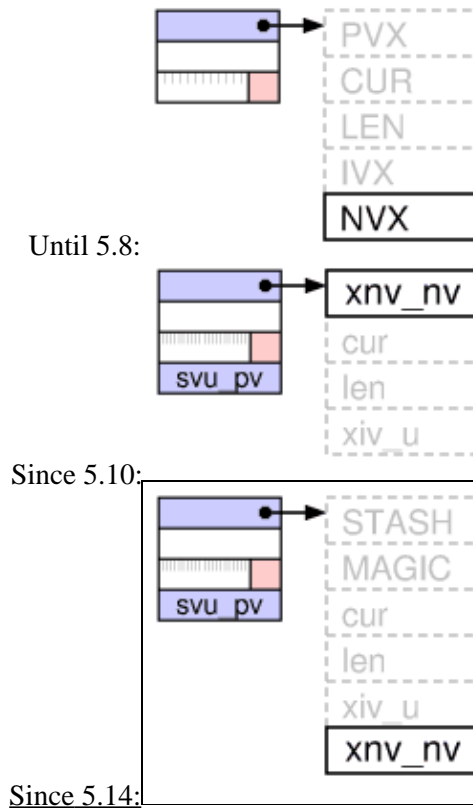

Since 5.10 for a raw IV (without PV) the IVX slot is in the HEAD, there is no xpviv struct ("body") allocated. The `SvIVX` macro abuses `SvANY` pointer arithmetic to point to a compile-time calculated negative offset from `HEAD-1` to `sv_u.svu_iv`, so that `PVIV` and `IV` can use the same `SvIVX` macro.

SvNV

Since 5.10 for a raw NV (without PV) the xpvnv struct is not fully allocated, only the needed body size.

SvRV

The *SvRV* type uses the fourth HEAD word `sv_u.svu_rv` as pointer to an SV (which can be any of the SvNULL subtypes), AV or HV. A SvRV object with ROK flag off represents an undefined value.

Since 5.10:

SvPVMG

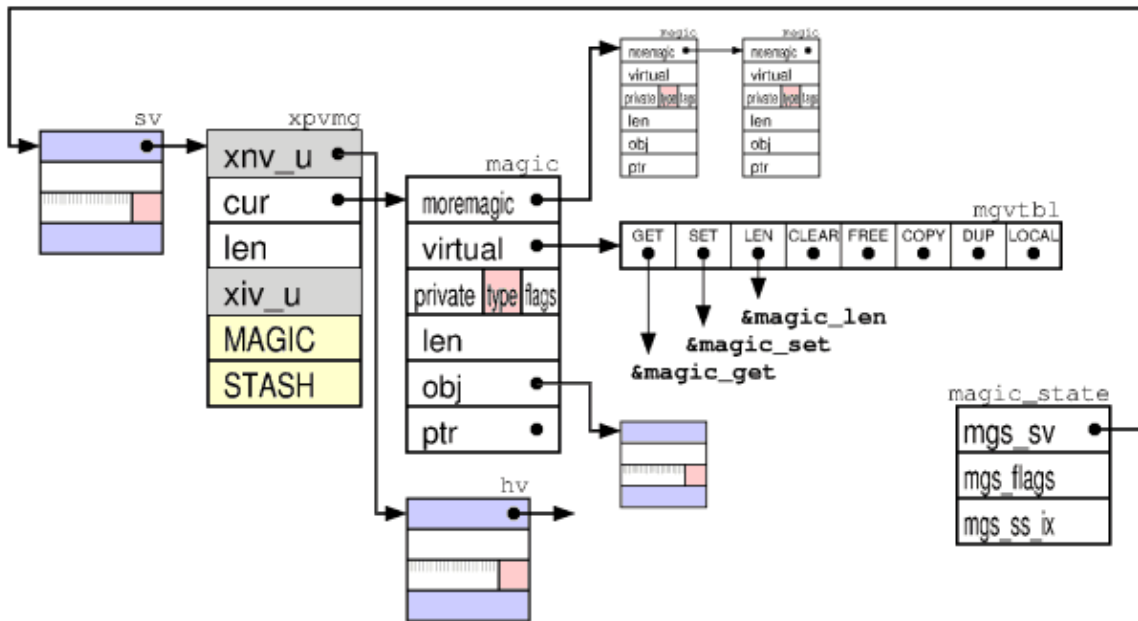

Blessed scalars or other magic attached. *SvPVMG* has two additional fields; **MAGIC** and **STASH**. **MAGIC** is a pointer to additional structures that contains callback functions and other data. If the **MAGIC** pointer is non-NULL, then one or more of the **MAGICAL** flags will be set.

STASH (symbol **table hash**) is a pointer to a **HV** that represents some namespace/class/package. (That the **HV** represents a namespace means that the **NAME** field of the **HV** must be non-NULL. See description of **HVs** and **stashes** below). The **STASH** field is set when the value is blessed into a package (becomes an object). The **OBJECT** flag will be set when **STASH** is. (*IMHO, this field should really have been named "CLASS". The **GV** and **CV** subclasses introduce their own unrelated fields called **STASH** which might be confusing.*)

Until 5.8:

Since

5.10:

Since

5.14:

The field `MAGIC` points to an instance of `struct magic` (typedefed as `MAGIC`). This struct has 8 fields:

1. `moremagic` is a pointer to another `MAGIC` and is used to form a single linked list of the `MAGIC`s attached to an SV.
2. `virtual` is a pointer to a struct containing 5-8 function pointers. The functions (if set) are invoked when the corresponding action happens to the SV.
3. `private` is a 16 bit number (U16) not used by Perl.
4. `type` is a character field and is used to denote which kind of magic this is. The interpretation of the rest of the fields depend on the `type` (actually it is the callbacks attached to `virtual` that do any interpretation). There is usually a direct correspondence between the `type` field and the `virtual` field.
5. `flags` contains 8 flag bits, where 2 of them are generally used. Bit 2 is the **REFCOUNTED** flag. It indicates that the `obj` is assumed to be an SV and that its reference count must be decremented when

this magic is freed. Self-referenced magic obj \Leftrightarrow sv have the REFCOUNTED flag not set, so that on destruction no self-ref'd loops can appear. The **GSKIP** flag indicate that invocation of the magical GET method should be suppressed. Other flag bits are used depending of the kind of magic.

6. *obj* is usually a pointer to some SV, *SvTIED_obj*. How it is used depends on the kind of magic this is.
7. *ptr* is usually a pointer to some character *MgPV* string. How it is used depends on the kind of magic this is. If the *len* field is ≥ 0 , then *ptr* is assumed to point to a malloced buffer and will be automatically freed when the magic is.
8. *len* is usually the length of the character string pointed to by *ptr*. How it is used depends on the kind of magic this is.

The struct `magic_state` is stored on the global savestack. *mgs_sv* points to our magical sv, and *mgs_ss_ix* points on the savestack after the saved destructor.

SvPVBM (old)

Since 5.10 *SvPVBM* are really *PVGVs*, with the **VALID** flag set, and "B" magic attached. Before *SvPVBM* where *SV* objects by their own.

The *SvPVBM* is like *SvPVMG* above. I uses the `xnv_u` union for three additional values in `xbm_s`; U32 *BmPREVIOUS*, U8 *BmUSEFUL*, U8 *BmRARE*. The *SvPVBM* value types are used internally to implement very fast lookup of the string in PVX using the "Boyer-Moore" algorithm. They are used by the Perl `index()` builtin when the search string is a constant, as well as in the RE engine. The `fbm_compile()` function turns normal *SvPVs* into this value type.

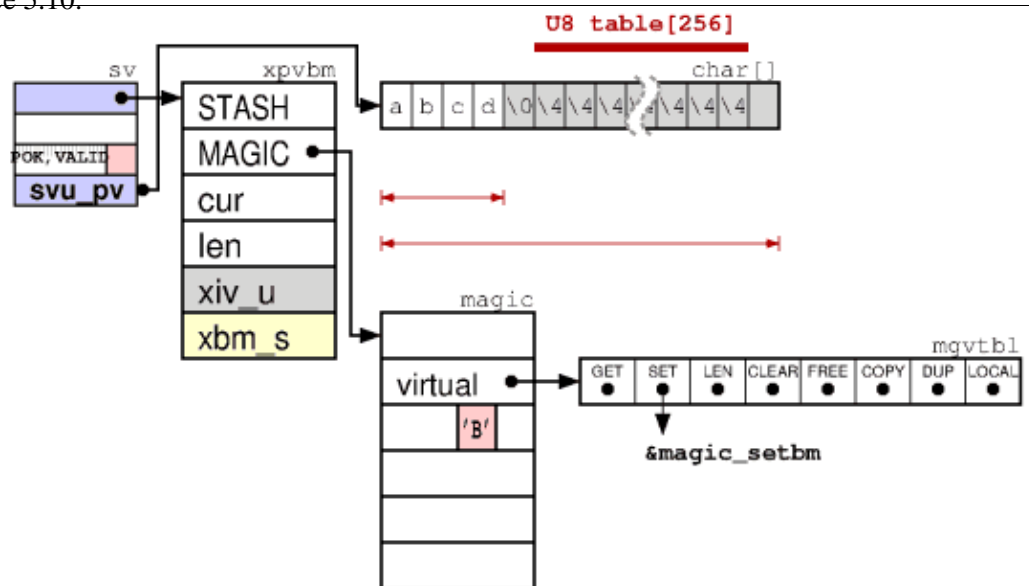

A table of 256 elements is appended to the PVX. This table contains the distance from the end of string of the last occurrence of each character in the original string. (In recent Perls, the table is not built for strings shorter than 3 character.) In addition `fbm_compile()` locates the rarest character in the string (using builtin letter frequency tables) and stores this character in the *BmRARE* field. The *BmPREVIOUS* field is set to the location of the first occurrence of the rare character. *BmUSEFUL* is incremented (decremented) by the RE engine when this constant substring (does not) help in optimizing RE engine access away. If it goes below 0, then the corresponding substring is forgotten and freed;

Until 5.8:

Since 5.10:

Since 5.14:

The extra SvPVBM information and the character distance table is only valid when the **VALID** flag is on. A magic structure with the sole purpose of turning off the VALID flag on assignment, is always attached to a *valid* SvPVBM.

The **TAIL** flag is used to indicate that the search for the SvPVMG should be *tail anchored*, i.e. a match should only be considered at the end of the string (or before newline at the end of the string).

REGEXP (P5RX)

The structures behind the P5RX, the *struct regexp*, store the compiled and optimized state of a perl regular expression. New here is support for pluggable regex engines - the original engine was critized ("*Thompson NFA for abnormal expressions would be linear, but does not support backtracking*"), non-recursive execution, and faster trie-structures for alternations. See re::engine::RE2 for the fast DFA implementation without backrefs.

The *struct regexp* contains the compiled bytecode of the expression, some meta-information about the regex, such as the used engine, the precomp and the number of pairs of backreference parentheses. *reg_data* contains

code and pad pointers for EXEC items in the bytecode.

Since 5.11 the REGEXP is separate from a PVMG, blessed into the "Regexp" package, with the SvANY pointing to the struct regexp, and SvPVX pointing to the string representation of the qr//.

Since 5.17.6 the SvANY ptr is the same as the SvPVX pointer, and the SvPVX pointer (i.e. `sv_u.svu_rx`) is now used to access the regexp via `ReANY()`.

Marc Jason Dominus - <http://perl.plover.com/Rx/paper/>

Nobody so far did a successful freeze/thaw of those internal structures, but we have Abhijit's `re_dup()` to clone a regexp, and we can simply recompile along

```
PM_SETRE(&pm, CALLREGCOMP(newSVpv($restring), $op->pmflags));
RX_EXTFLAGS(PM_GETRE(&pm)) = $op->reflags;
```

BTW: Marc-Jason Dominus implemented a debugger for the compiled Rx bytecode <http://perl.plover.com/Rx/paper/>.

See **perlreguts** for some details.

SvPVLV

The `SvPVLV` is like `SvPVMG` above, but has four additional fields; `TARGOFF`, `TARGLEN`, `TARG`, `TYPE`. The typical use is for Perl builtins that can be used in the LValue context (`substr`, `vec`,...). They will return an `SvPVLV` value, which when assigned to use magic to affect the *target* object, which they keep a pointer to in the `TARG` field. The `xiv_u` union is used as the `GvNAME` field, pointing to a `namehek`.

The `TYPE` is a character variable. It encodes the kind of LValue this is. Interpretation of the other LValue fields depend on the `TYPE`. The `SvPVLVs` are (almost) always magical. The magic type will match the `TYPE` field of the `SvPVLV`. The types are:

'x'

Type-x LVs are returned by the `substr($string, $offset, $len)` builtin.

'v'

Type-v LVs are returned by the `vec($string, $offset, $bits)` builtin.

':'

Type-: LVs are returned by the `pos($scalar)` builtin.

'k'

Type-k LVs are returned when `keys %hash` is used on the left side of the assignment operator.

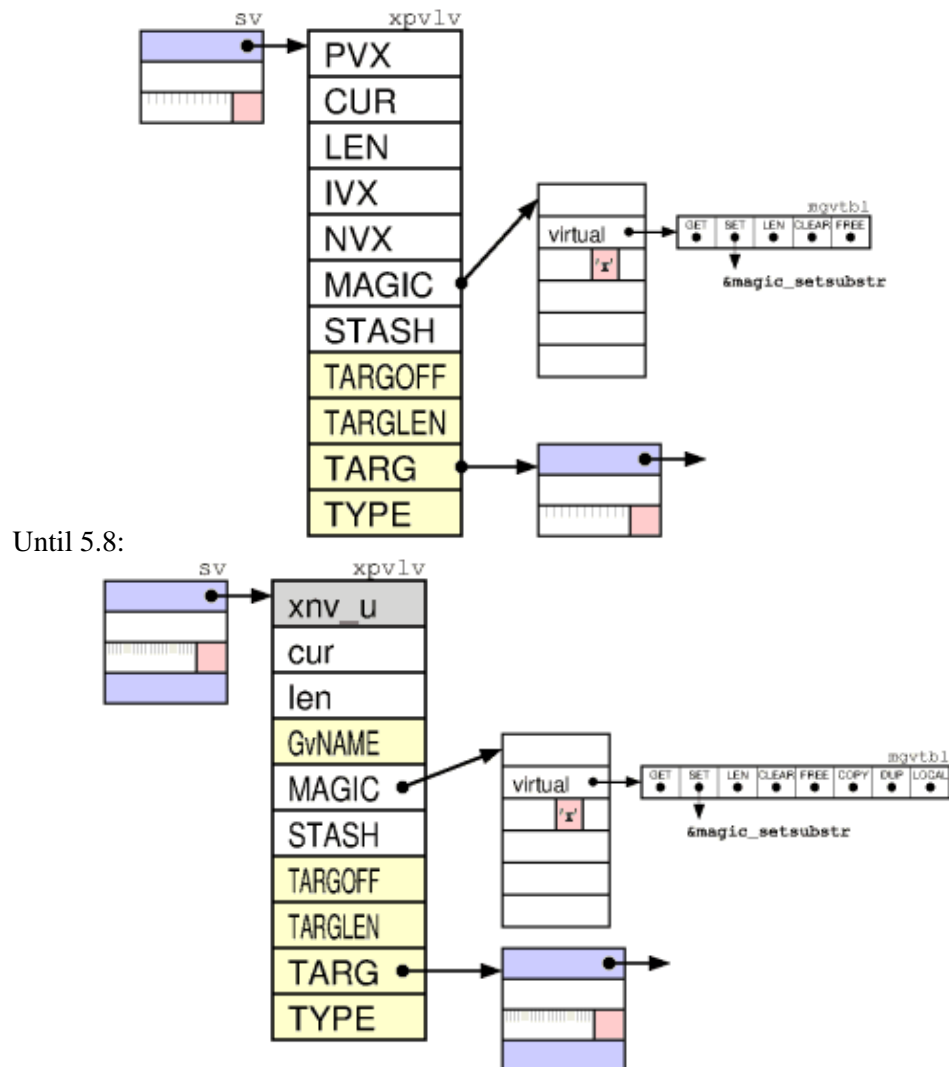

'y'

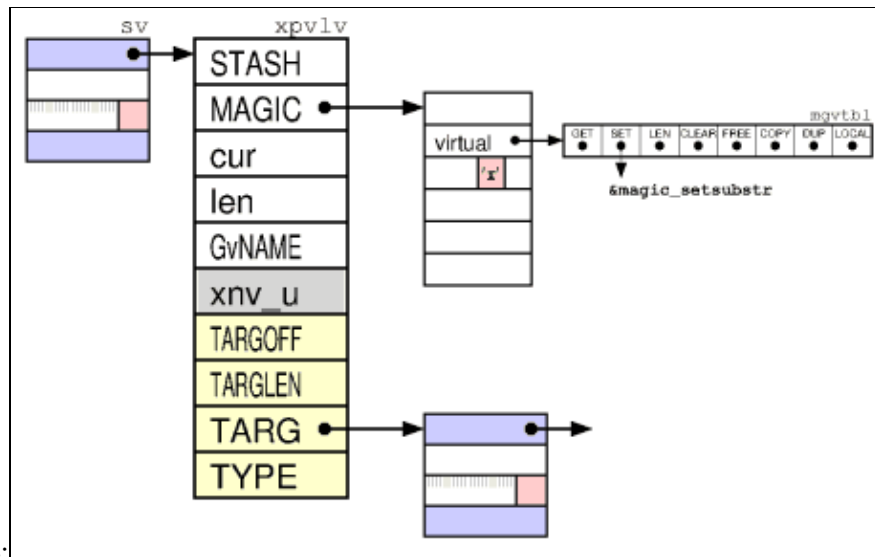

Type-y LVs are used by auto-vivification (of hash and array elements) and the `foreach` array iterator variable.

'/'

Used by `pp_pushre`. (*I don't understand this yet.*)

The figure below shows an SvPVLV as returned from the `substr()` builtin. The first `substr` parameter (the string to be affected) is assigned to the TARG field. The `substr` offset value goes in the TARGOFF field and the `substr` length parameter goes in the TARGLEN field.

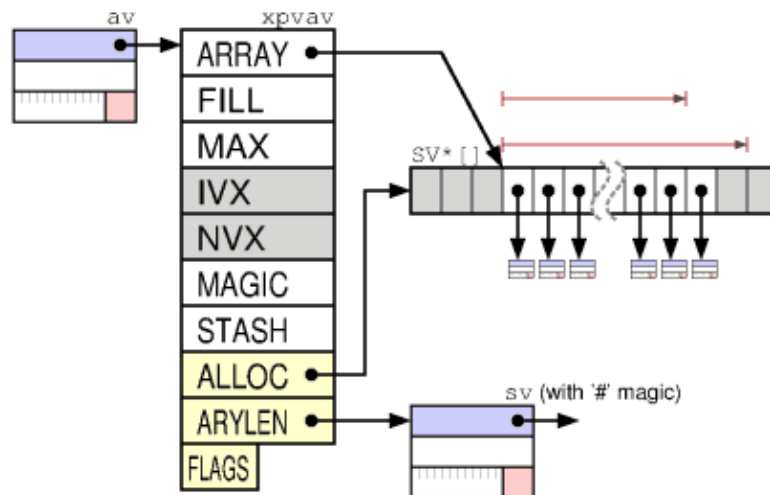

Since 5.14:

When assignment to an `SvPVLV` type occurs, then the value to be assigned is first copied into the `SvPVLV` itself (and affects the `PVX`, `IVX` or `NVX`). After this the magic `SET` method is invoked, which will update the `TARG` accordingly.

AV

An array is in many ways represented similar to strings. An `AV` contains all the fields of `SvPVMG`, but not more. Some fields of `xpvav` and `sv` have been renamed. `ARYLEN` uses the `MAGIC` field, to point to a magic `SV` (which is returned when `$#array` is requested) and is only created on demand. `IVX` has become `ALLOC`, which is a pointer to the allocated array. `PVX` in the `sv_u` has become `ARRAY`, the direct pointer the the current array start, `CUR` has become `FILL` and `LEN` has become `MAX`. One difference is that the value of `FILL/MAX` is always one less than `CUR/LEN` would be in a `SVPV`. The `NVX` field is unused.

The previous extra `FLAGS` field in the `xpvav` has been merged into the `sv_flags` field.

Until 5.8:

PerlGuts Illustrated

Since 5.10:

Since 5.14:

The array pointed to by `ARRAY` contains pointers to any of the `SvNULL` subtypes. Usually `ALLOC` and `ARRAY` both point to the start of the allocated array. The use of two pointers is similar to the `OOK` hack described [above](#). The shift operation can be implemented efficiently by just adjusting the `ARRAY` pointer (and `FILL/MAX`). Similarly, the pop just involves decrementing the `FILL` count.

There are only 2 array flags defined:

SVpav_REAL

It basically means that all SVs contained in this array is owned and must have their reference counters decremented when the reference is removed from the array. All normal arrays are `REAL`. For the `stack` the `REAL` flag is turned off. For `@_` the `REAL` flag is initially turned off.

SVpav_REIFY

The array is *not* `REAL` but should be made `REAL` if modified. The `@_` array will have the `REIFY` flag turned on.

HV

Hashes are the most complex of the Perl data types. In addition to what we have seen above, the very last index in the `HE*[]` points to a new `xpvhv_aux` struct. HVs use `HE` structs to represent "hash element" key/value pairs and `HEK` structs to represent "hash element keys".

RITER, EITER:

Those two fields are used to implement a single iterator over the elements in the hash. `RITER` which is an integer index into the array referenced by `ARRAY` and `EITER` which is a pointer

to an HE. In order find the next hash element one would first look at EITER->next and if it turns out to be NULL, RITER is incremented until ARRAY[RITER] is non-NULL. The iterator starts out with RITER = -1 and EITER = NULL.

NAME:

Until 5.8 NAME was a NUL-terminated string which denotes the fully qualified name of the name space (aka *package*). This was one of the few places where Perl did not allow strings with embedded NULs.

Since 5.10 the value of NAME points to a HEK, and since 5.14 to one HEK if name_count == 0, or to two HEKs, where HEK[0] is the effective stash name (HvENAME_HEK_NN) if name_count > 0 or HEK[1] if name_count < 0.

GvSTASH (until 5.8):

When the hash represented a name space (*stash*) GvSTASH (formerly called PMROOT) pointed to a node in the Perl syntax tree. It was used to implement the reset() builtin for REs.

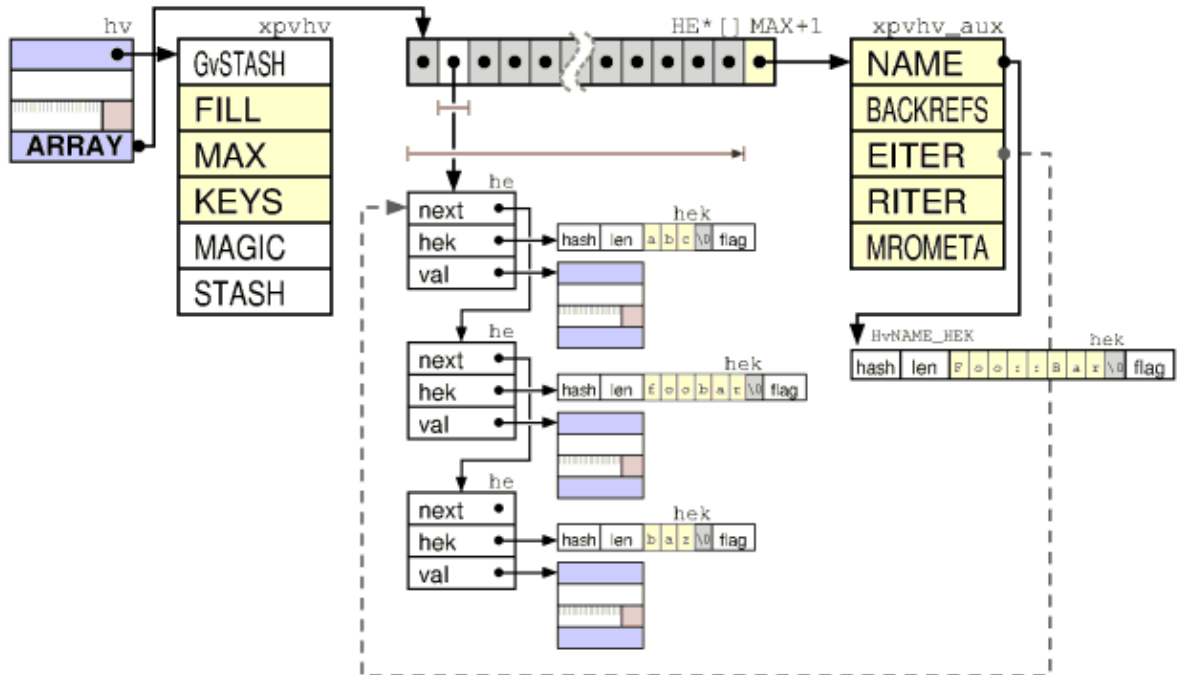

The first few fields of the `xpvhv` have been renamed in the same way as for AVs. **MAX** is the number of elements in **ARRAY** minus one. (The size of the **ARRAY** is required to be a power of 2, since the code that deals with hashes just mask off the last few bits of the **HASH** value to locate the correct **HE** column for a key: **ARRAY[HASH & MAX]**). Also note that **ARRAY** can be **NULL** when the hash is empty (but the **MAX** value will still be at least 7, which is the minimum value assigned by Perl.)

The **FILL** is the number of elements in ARRAY which are not NULL. The IVX field has been renamed **KEYS** and is the number of hash elements in the HASH.

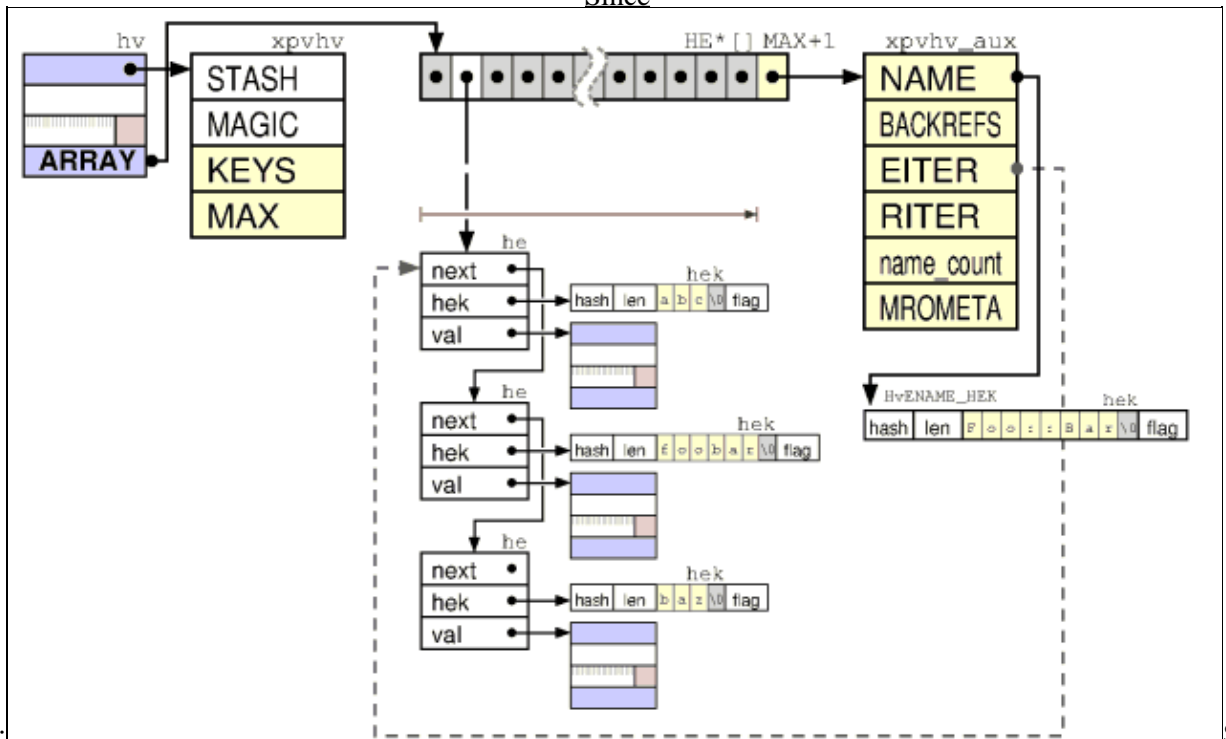

Until 5.8:

Since

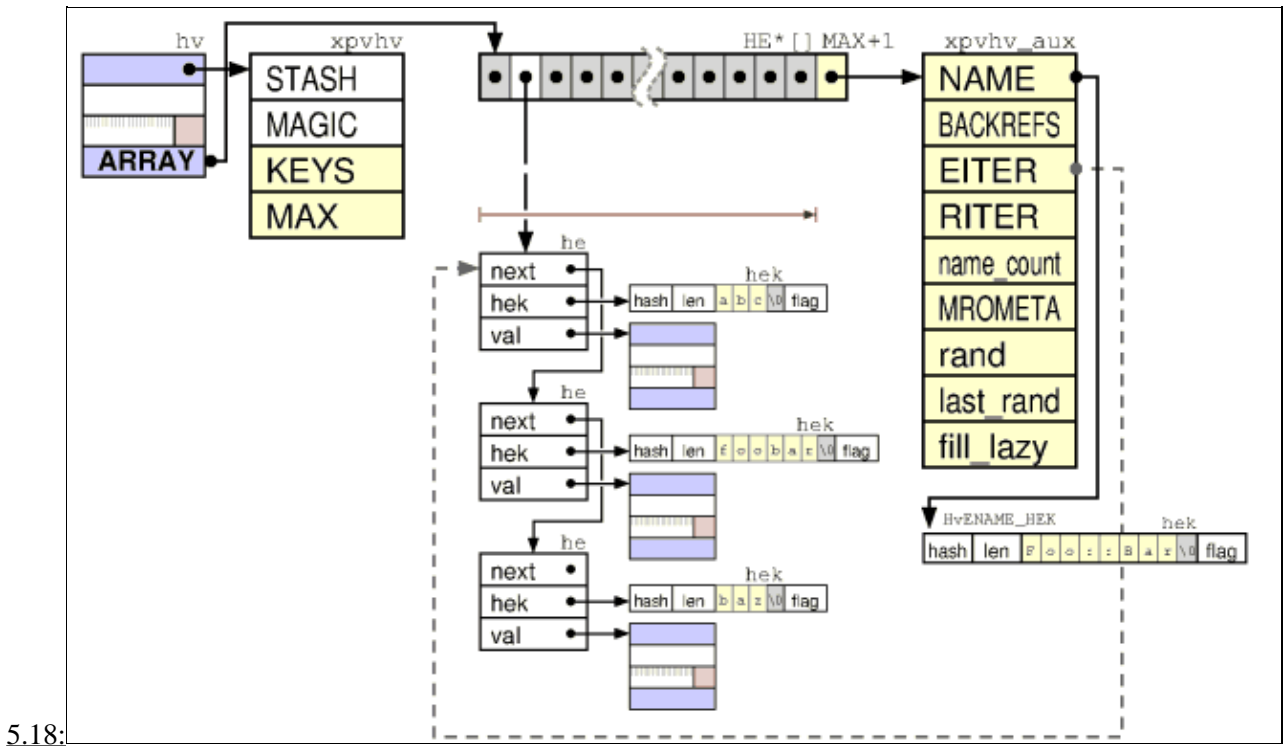

5.10:

Since

5.14:

Since

The **HE**s are simple structs containing 3 pointers. A pointer to the next HE, a pointer to the key and a pointer to the value of the given hash element.

The **HEK**s are special variable sized structures that store the hash keys. They contain 4 fields. The computed *hash* value of the string, the *length* of the string, *len*+1 bytes for the key string itself (including trailing NUL), and a trailing byte for HEK_FLAGS (*since* 5.8). As a special case, a *len* value of HEf_SVKEY (-2) indicate that a pointer to an SV is stored in the HEK instead of a string. This hack is used for some magical hashes.

In a perfect hash both KEYS and FILL are the same value. This means than all HEs can be located directly from the pointer in the ARRAY (and all the *he*->*next* pointers are NULL).

The following two hash specific flags are found among the common SvNULL flags:

0x20000000 **SVphv SHAREKEYS**

When this flag is set, then the hash will share the HEK structures with a special hash pointed to by the *strtab* variable. This reduce the storage occupied by hash keys, especially when we have lots of hashes with the same keys. The SHAREKEYS flag is on by default for newly created HVs.

PerlGuts Illustrated

What is special with the `strtab` hash is that the `val` field of the HE structs is used as a reference counter for the HEK. The counter is incremented when new hashes link up this HEK and decremented when the key is removed from the hashes. When the reference count reach 0, the HEK (and corresponding HE) is removed from `strtab` and the storage is freed.

0x40000000 **SVphv LAZYDEL**

This flag indicates that the hash element pointed to by EITER is really deleted. When you delete the current hash element, perl only marks the HV with the LAZYDEL flag, and when the iterator is advanced, then the element is zapped. This makes it possible to delete elements in a hash while iterating over it.

GV

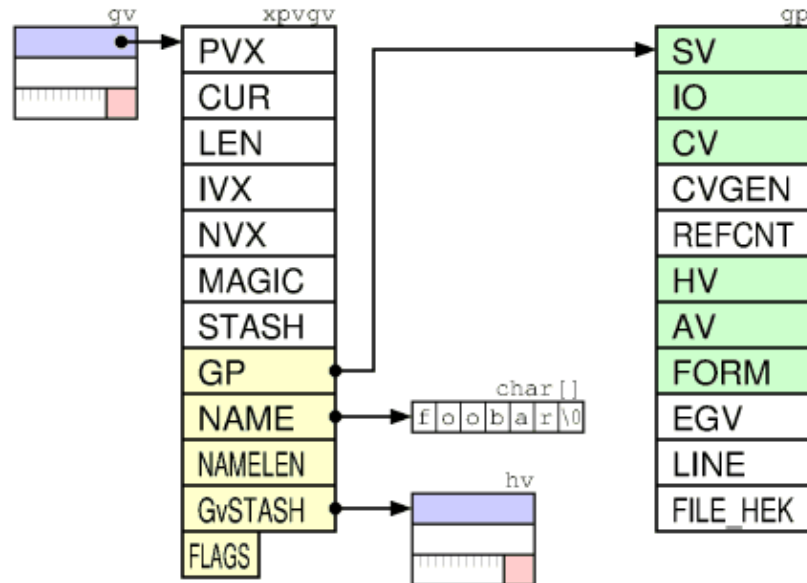

GV ("glob value" aka "symbol") shares the same structure as the `SvPVMG`.

The `GP` is a pointer to structure that holds pointers to data of various kinds. Perl use a pointer, instead of including the GP fields in the `xpvgv`, in order to implement the proper glob aliasing behavior (i.e. different GVs can share the same GP).

The `NAMEHEK` denotes the unqualified name of this symbol and `GvSTASH` points to the symbol table where this symbol belongs. The fully qualified symbol name is obtained by taking the `NAME` of the `GvSTASH` (see `HV` above) and appending `::` and `NAME` to it. The hash pointed to by `GvSTASH` will usually contain an element with `NAME` as key and a pointer to this GV as value. See description of [stashes](#)

below.

A magic of type '*' is always attached to the GV (not shown in the figure). The magic GET method is used to stringify the globs (as the fully qualified name prefixed with '*'). The magic SET method is used to alias an GLOB based on the name of another glob.

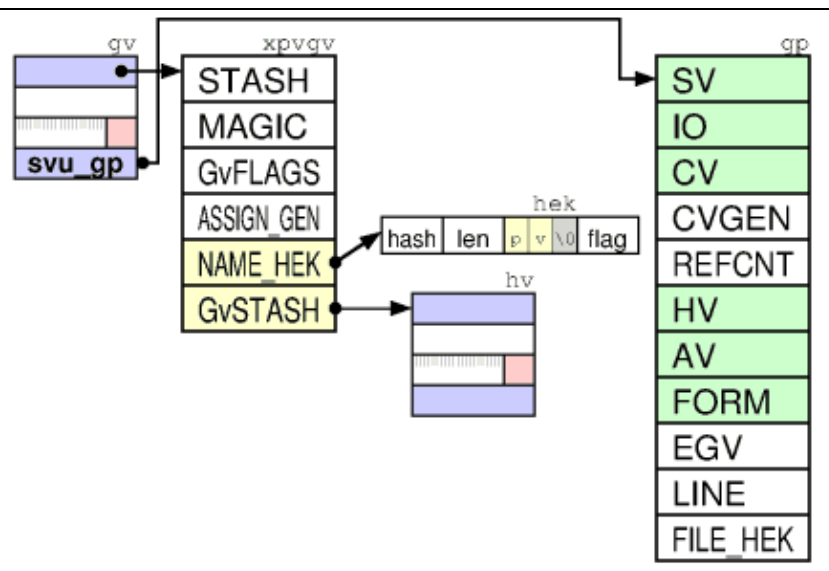

Until 5.8:

PerlGuts Illustrated

Since 5.10:

Since 5.14:

GvFLAGS:

0x1) **INTRO**

0x2) **MULTI**

Have we seen more than one occurrence of this glob. Used to implement the "possibly typo" warning.

0x4) **ASSUMECV** The GV is most likely a CV.

0x8) **IN_PAD** With ithreads new GVs are created temporary on the PAD, and not as global SV.

0x10) **IMPORTED_SV**

0x20) **IMPORTED_AV**
 0x40) **IMPORTED_HV**
 0x80) **IMPORTED_CV**

GP

GPs can be shared between one or more GVs. The data type fields for the GP are: SV, IO, FORM, AV, HV, CV. These hold a pointer to the corresponding data type object. (The SV must point to some simple SvNULL subtype (i.e. with type <= SVt_PVLV). The FORM field must point to a SvPVFM if non-NULL. The IO field must point to an IO if non-NULL, the AV to an AV, etc.) The SV is always present (but might point to a SvNULL object). All the others are initially NULL.

The additional administrative fields in the GP are: CVGEN, REFCNT, EGV, LINE, FILE_HEK.

REFCNT is a reference counter. It says how many GVs have a pointer to this GP. It is incremented/decremented as new GVs reference/forget this GP. When the counter reach 0 the GP is freed.

EGV, the "effective gv", if *glob, is a pointer to the GV that originally created this GP (used to tell the real name of any aliased symbol). If the original GV is freed, but GP should stay since another GV reference it, then the EGV is NULLED.

CVGEN is an integer used to validate method cache CV entries in the GP. If CVGEN is zero, then the CV is real. If CVGEN is non-zero, but less than the global variable `subgeneration`, then the CV contains a stale method cache entry. If CVGEN is equal to `subgeneration` then the CV contains a valid method cache entry.

Every time some operation that might invalidate some of the method caches are performed, then the `subgeneration` variable is incremented.

FILE_HEK is the name of the file where this symbol was first created.

LINE is the corresponding line number in the file.

Stashes

GVs and stashes work together to implement the name spaces of Perl. Stashes are named HVs with all the element values being pointers to GVs. The root of the namespace is pointed to by the global variable `defstash`.

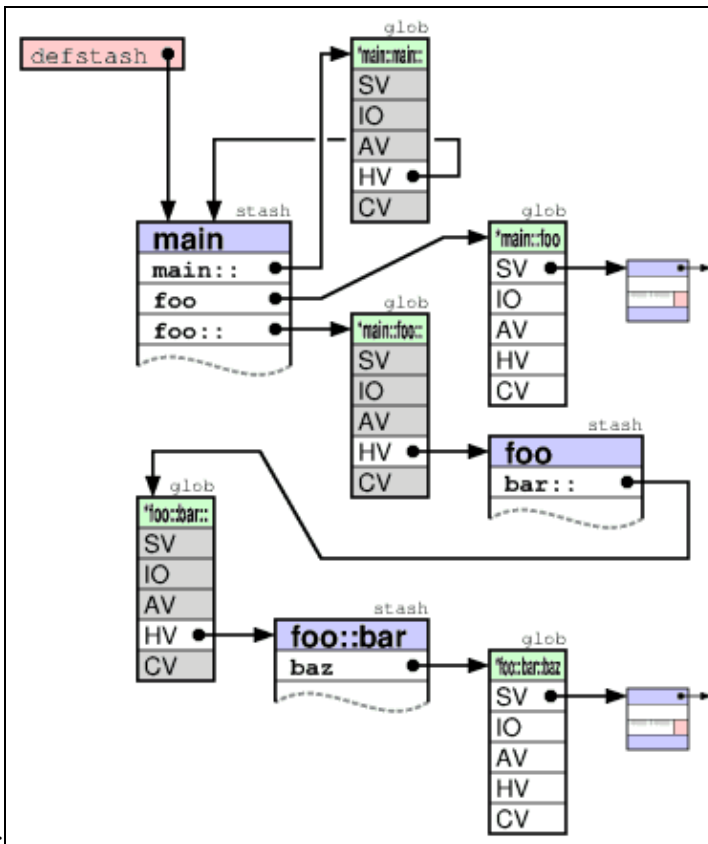

In the figure below we have simplified the representation of stashes to a single box. The text in the blue field is the NAME of the HV/stash. The hash elements keys are shown as field names and the element values are shown as pointers to globs (GV). The GVs are also simplified to a single box. The text in the green field in the fully qualified name of the GV. Only the GP data fields are shown (and FORM has been eliminated because it was not 2 letters long :-).

The figure illustrates how the scalar variables `$::foo` and `$foo::bar::baz` are represented by Perl.

PerlGuts Illustrated

Until 5.8:

Since 5.10:

All resolution of qualified names starts with the stash pointed to by the `defstash` variable. Nested name spaces are implemented by a stash entry with a key ending in `::`. The entry for `"main::"` ensures that

`defstash` is also known as "main" package (and has the side-effect that the "main::main::main" package is `defstash` too.) Unqualified names are resolved starting at `curstash` or `curcop->cop_stash` which are influenced by the `package` declaration in Perl.

As you can see from this figure, there are lots of pointers to dereference in order to look up deeply nested names. Each stash is at least 4 levels deep and each glob is 3 levels, giving at least 24 pointer dereferences to access the data in the `$foo::bar::baz` variable from `defstash`.

The `defstash` stash is also a place where globs representing source files are entered. These entries are prefixed with "`_<`". The `FILEGV` field of the GP points to the same glob as the corresponding "`_<`" entry in `defstash` does.

CV

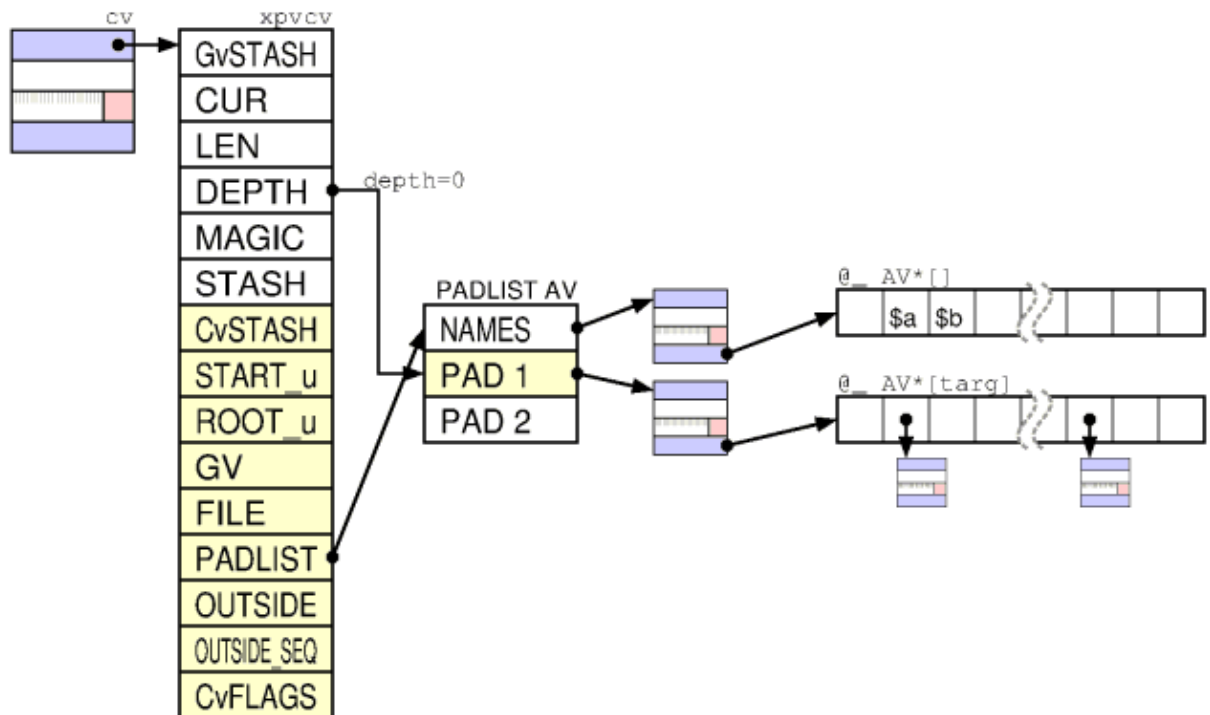

The CV ("code value") is like `$vPVMG` above, but has some renamed and additional fields; `CvSTASH`, `START`, `ROOT`, `GV`, `FILEGV`, `DEPTH`, `PADLIST`, `OUTSIDE`, `OUTSIDE_SEQ`, `CvFLAGS`.

Until

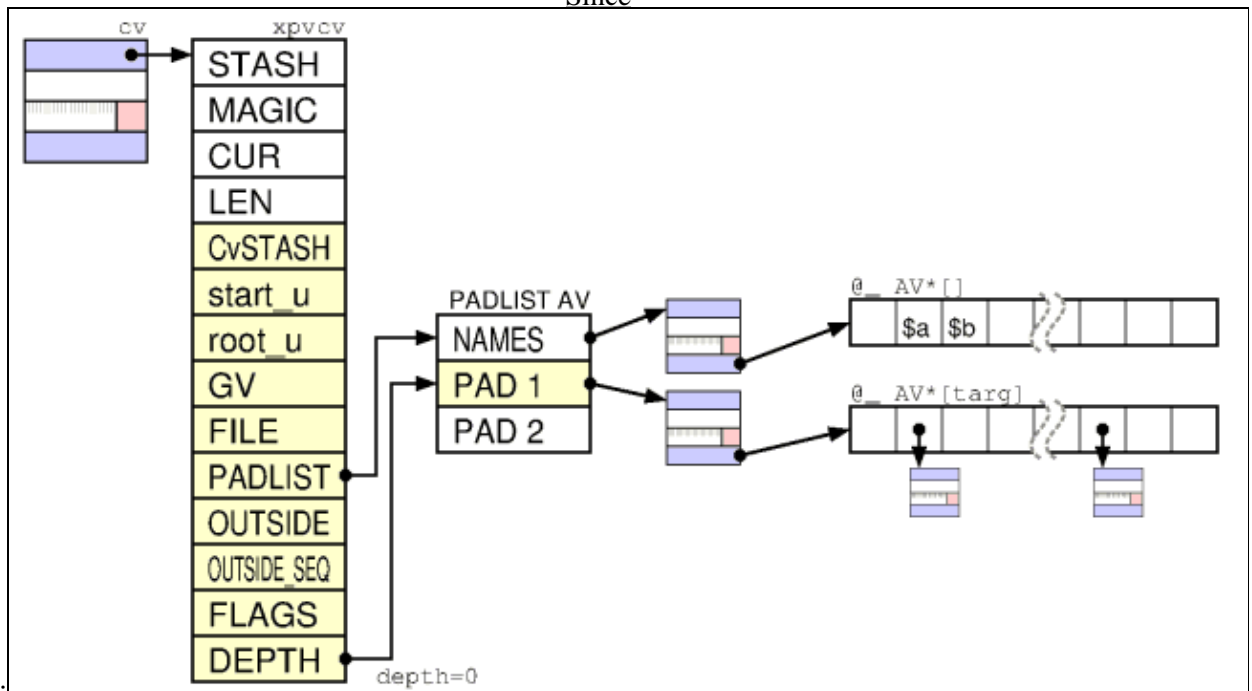

5.8:

Since

5.10:

Since

5.14:

The **CvSTASH** is a pointer to the stash in which the CV was *compiled*.

START and **ROOT** point to the start and the root of the compiled op tree for this function.

DEPTH and **PADLIST** are needed to access and check the current scratchpad. Lexicals are accessed by the **OP->targ** index into the **PADLIST**.

See **PADs** and **OPs** below.

SvPVFM

The *SvPVFM* is like *CV* above, but adds a single field called *LINES*.

IO

The *IO* is like *SvPVMG* above, but has quite a few additional fields.

PerlGuts Illustrated

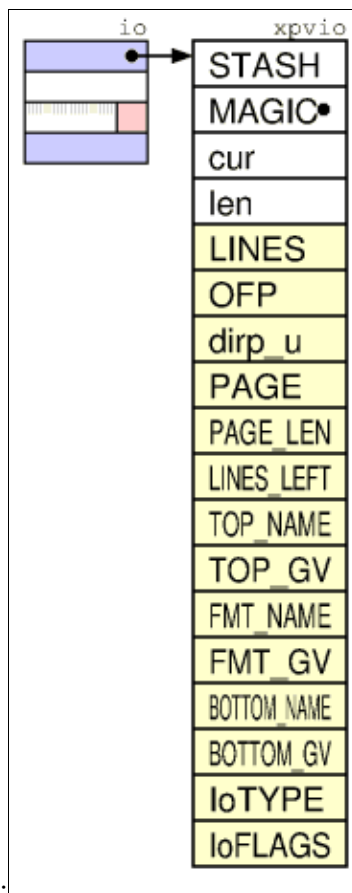

Until 5.8:

PerlGuts Illustrated

Since 5.10:

Since 5.14:

IoFLAGS

- 1 IOf_ARGV this fp iterates over ARGV
- 2 IOf_START check for null ARGV and substitute '-'
- 4 IOf_FLUSH this fp wants a flush after write op
- 8 IOf_DIDTOP just did top of form
- 16 IOf_UNTAINT consider this fp (and its data) "safe"
- 32 IOf_NOLINE slurped a pseudo-line from empty file
- 64 IOf_FAKE_DIRP xio_dirp is fake (source filters kludge)

PAD

A PAD is a list (AV) of elements for Perl variables for each subroutine. PADs ("Scratchpads") are used by Perl to store lexical variables, op targets and constants. Every TARG argument for an OP (see below) is an index into the PAD, and each recursion level has its own PAD.

Each new sub creates a **PADLIST** of length 1, which points to current PAD, the **PL_curpad**, indexed by **TARG**. The 0'th entry of the **CvPADLIST** is an AV which represents the "names" or rather the "static type information" for lexicals.

The **CvDEPTH**'th entry of **CvPADLIST** AV is an AV which is the stack frame at that depth of recursion into the CV. The 0'th slot of a frame AV is an AV which is **@_**. Other entries are storage for variables and op targets, the scratchpads.

During compilation a simplified scratchpad is used. The current **PL_comppad** is just a PAD which holds the **TARG** variables directly, without indirection which is needed for run-time recursion and threading.

During compilation: **PL_comppad_name** is set to the names AV, the declared type information.

PL_comppad is set to the frame AV for the frame **CvDEPTH == 1**. **PL_curpad** is set to the body of the frame AV (i.e. **AvARRAY(PL_comppad)**).

During execution, **PL_comppad** and **PL_curpad** refer to the live frame of the currently executing sub.

Since 5.18 PADLISTs are refcounted, with a separate **struct padlist**, not depicted here yet.

Lexicals (my and our variables) have **SVs_PADMY** / **SVs_PADOUR** set, and targets have **SVs_PADTMP** set. A **SVs_PADTMP** (targets/GVs/constants) has a **&PL_sv_undef** name, as they are looked up by the **TARG** index, only **SVs_PADMY** / **SVs_PADOUR** get valid names.

OP

A Perl program/subroutine is represented internally by a syntax tree built from OP nodes. This tree really is just a linked list of ops in *exec* order. Perl 5.005 had 346 different OP-codes, Perl 5.16 has 372 OP-Codes, see **opnames.h**. Each op represents a **pp_opname()** function. Note that some **pp_** functions are just macros, several opcodes share the same function.

In Perl there are 12 different OP classes, that are related like the following class hierarchy diagram shows:

PerlGuts Illustrated

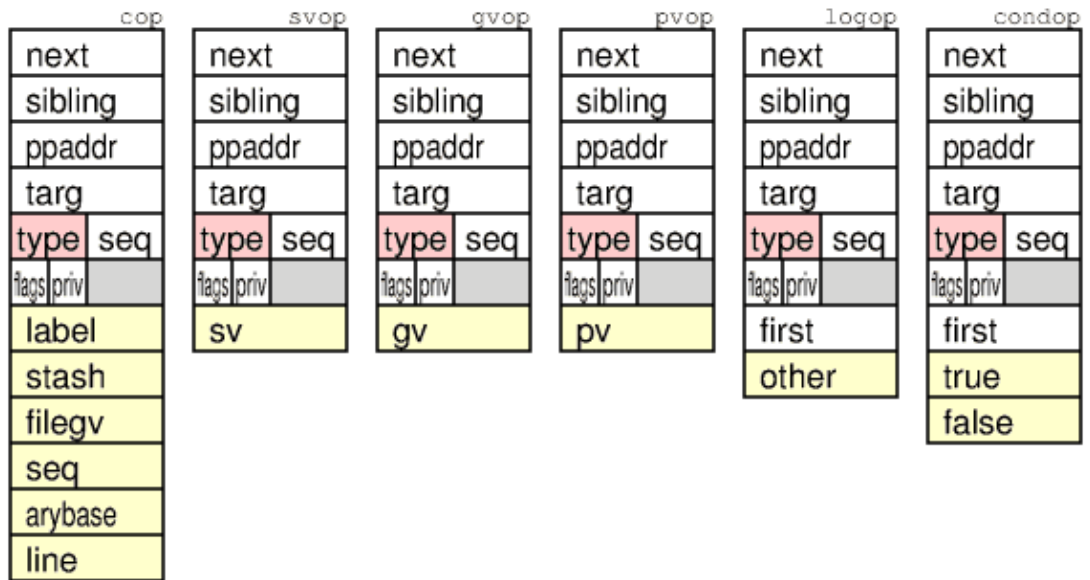

op	unop	binop	listop	pmop	loop
next	next	next	next	next	next
sibling	sibling	sibling	sibling	sibling	sibling

Since 5.10:

PerlGuts Illustrated

Until 5.8:

Since 5.10:

A typical small optree for `$a = $b + 42` would be:

```
$ perl-nonthreaded -MO=Concise -e '$a = $b + 42' $ perl-nonthreaded -MO=
8  <@> leave[1 ref] vKP/REFC ->(end)      1  <0> enter
1    <0> enter ->2                        2    <;> nextstate(main
2    <;> nextstate(main 1 -e:1) v:{ ->3    3    <$> gvsv(*b) s
7    <2> sassign vKS/2 ->8                 4    <$> const(IV 42) s
5      <2> add[t1] sK/2 ->6                 5    <2> add[t1] sK/2
-        <1> ex-rv2sv sK/1 ->4              6    <$> gvsv(*a) s
3          <$> gvsv(*b) s ->4              7    <2> sassign vKS/2
4          <$> const(IV 42) s ->5           8    <@> leave[1 ref] vK
-        <1> ex-rv2sv sKRM*/1 ->7
6          <$> gvsv(*a) s ->7
```

(Note: *ex-ops* are Nullified)

We have two BINOPs, SASSIGN and ADD as <2> and three SVOPs, GVSV and CONST as <\$>. *Note that for a threaded perl the GVSV OPs would have been PADOPs.* A SVOP pushes a SV onto the stack. A BINOP takes two args from the stack, and pushes a result.

B::Concise Types:

argnum:	opclass:	parsed op_flags:
S scalar	0 baseop	v Want void
L list	1 unop	s Want scalar (single value)
A array value	2 binop	l Want list of any length
H hash value	logop	K Kids
C code value	@ listop	P Parens, or block needs explicit scope ent
F file value	/ pmop	R REF
R scalar reference	\$ svop_or_padop	M MOD. Will modify (lvalue)
	# padop	S Stacked. Some arg is arriving on the stack
	" pvop_or_svop	* Special. Do something weird for this op
	{ loop	
	; cop	
	% baseop_or_unop	
	- filestatop	
	} loopexop	

A word on **cop.cop_warnings**: The numeric value of lexical warnings can be special: 0, 1 or 2 and is then stored in pointer pointed to by cop_warnings. cop_warnings may also hold a string buffer of a bitmask of warning categories. Since 5.10 this string buffer is in the second word of cop_warnings, the length is then stored in the first word. (i.e a pascal string)

For syntax trees and OP codes also see http://www.perlfoundation.org/perl5/index.cgi?optree_guts and http://books.simon-cozens.org/index.php/Perl_5_Internals.

Stacks

During compilation and runtime Perl use various stacks to manage itself and the program running. Several data stacks (variable scope and subroutine arguments), and also code context stacks (block context).

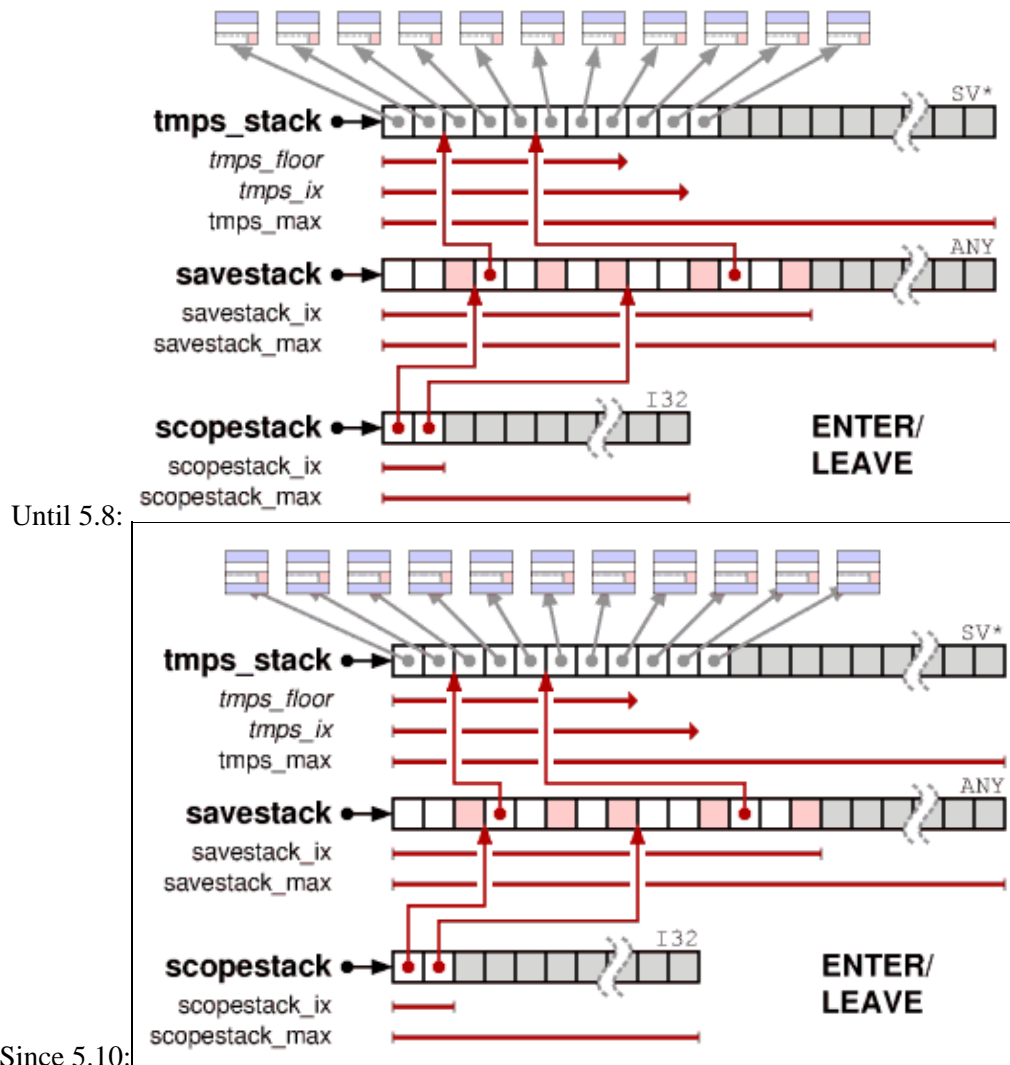

Scope

The first three data stacks implement **scopes**, including variables and values which are restored (or actions to be performed) when the scope is left.

The **scopestack** pushes the **savestack_ix** when ENTER is executed. On LEAVE the top **savestack_ix** entry is popped and all things saved on the **savestack** since this is restored. This means that a ENTER/LEAVE pairs represents dynamic nestable scopes.

The **savestack** contains records of things saved in order to be restored when the scopes are left. Each record consist of 2-4 ANY elements. The first one is a type code, which is used to decide how long the record is and how to interpret the other elements. (In the figure the type codes are marked pinkish color.) The restoring involves updating memory locations of various types as well as more general callbacks (destructors).

The **tmps_stack** implement mortal SVs. Each time a new mortal is made, then **tmps_ix** is incremented and the corresponding entry in **tmps_stack** made to point to it. When **SAVETMPS** is executed, then the old **tmps_floor** value is saved on the **savestack** and then **tmps_floor** is set equal to **tmps_ix**. When **FREETMPS** is executed, then all SVs pointed to by the pointers between **tmps_floor** and **tmps_ix** will have their **REFCNT** decremented. How many this will be depend on how many scopes has been left. Note that the **tmps_floor** and **tmps_ix** values is the index of the last SV* pushed. They both start out as -1 when the stack is empty.

The @_ stack

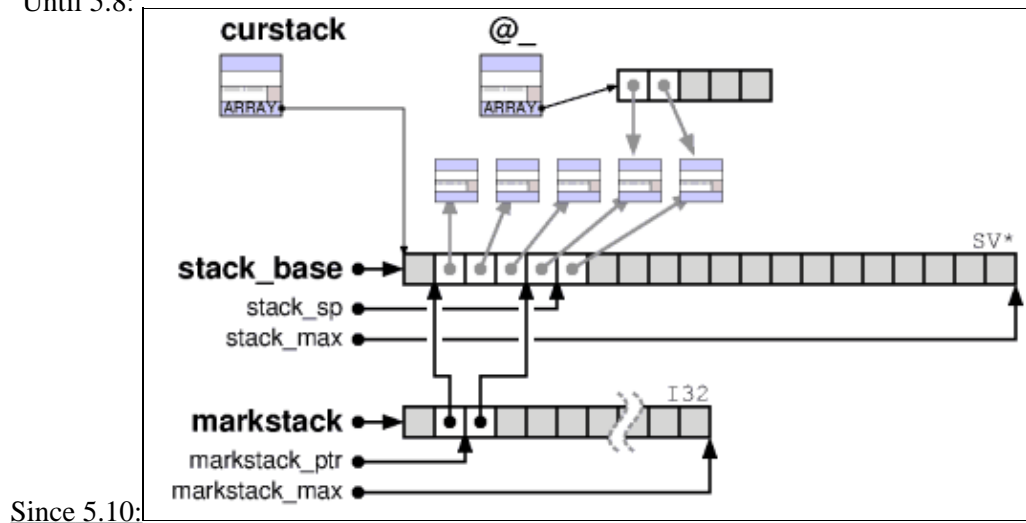

The next two stacks handle the arguments passed to subroutines, also the return values.

The first one is simply denoted as **the stack** and is really an AV. The variable **curstack** points to this AV. To speed up access Perl also maintain direct pointers to the start (**stack_base**) and the end (**stack_max**) of the allocated ARRAY of this AV. This AV is so special that it is marked as not **REAL** and the **FILL** field is not updated. Instead we use a dedicated pointer called **stack_sp**, the stack pointer. The stack is used to pass arguments to PP operations and subroutines and is also the place where the result of these operations as well as subroutine return values are placed.

The **markstack** is used to indicate the extent of the stack to be passed as `@_` to Perl subroutines. When a subroutine is to be called, then first the start of the arguments are marked by pushing the `stack_sp` offset onto **markstack**, then the arguments themselves are calculated and pushed on the stack. Then the `@_` array is set up with pointers the `SV*` on the stack between the **MARK** and `stack_sp` and the subroutine starts running. For `XSUB` routines, the creation of `@_` is suppressed, and the routine will use the **MARK** directly to find its arguments.

Until 5.8:

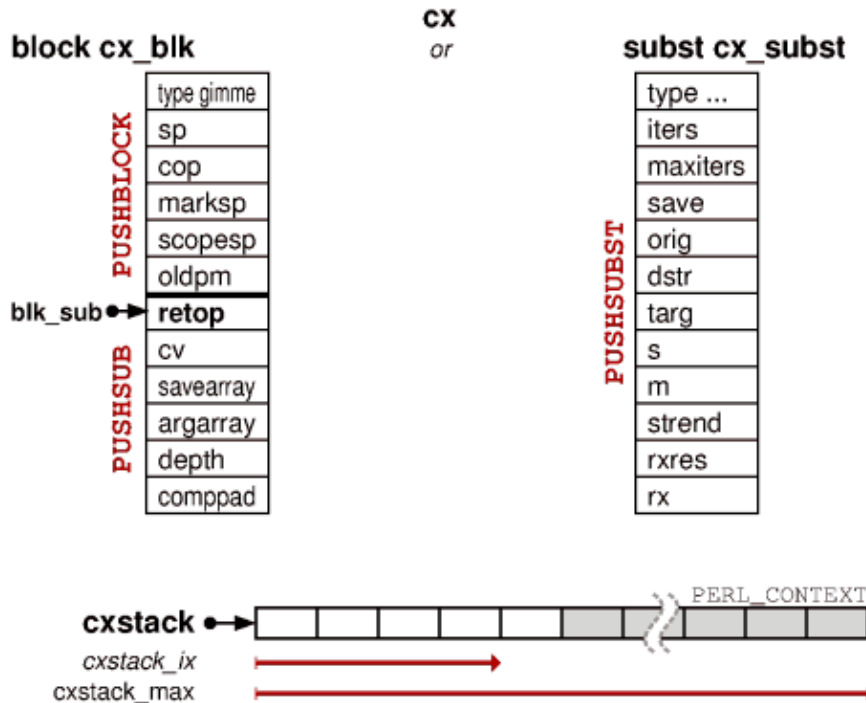

Since 5.10:

Context

The **cxstack** for *context stack* contains CX records that describe the current block context. Each time a subroutine, an eval, a loop, a format block or given/when block is entered, then a new PERL_CONTEXT cx record is pushed on the **cxstack**. When the context block finished at any LEAVE* op, then the top record is pop'ed and the corresponding values restored.

A cxstack record, the cx, is either a block context or subst context. A block context has a common header of size 6 and shares then structs for sub, format, eval, loop or given/when contexts also of size 6. The subst context is of size 12.

sub

The context setup for a Perl or XS subroutine does at **entersub**:

```
ENTER;
PUSHBLOCK(cx, CXt_SUB, SP);
PUSHSUB(cx);
cx->blk_sub.retop = PL_op->op_next;
CvDEPTH(cv)++;
SAVECOMPPAD();
PAD_SET_CUR_NOSAVE(CvPADLIST(cv), CvDEPTH(cv));
/* push args */
/* call sub */
```

and at **leavesub**

```
/* pop return value(s) */
POPBLOCK(cx, newpm);
LEAVE;
```

```

cxstack_ix--;
POPSUB(cx,sv);          /* release CV and @_ ... */
PL_curpm = newpm;       /* ... and pop $! et al */
LEAVESUB(sv);
return cx->blk_sub.retop;

```

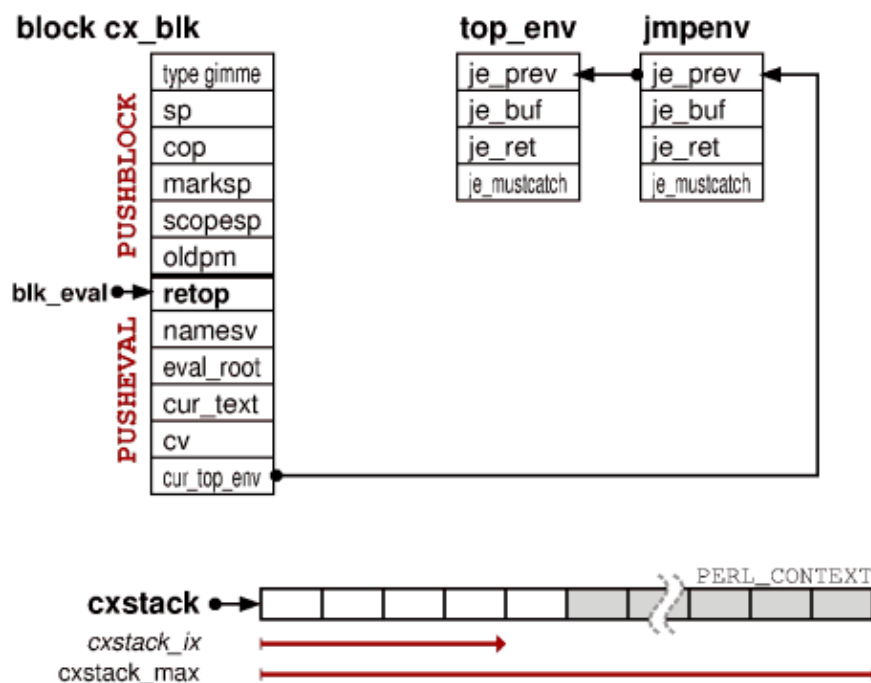

The *ENTER/LEAVE* pair handles the scope- and savestack.

The *PUSHBLOCK/POPBLOCK* pair handles the *cxstack* header of the current context, the special *blk_sub* values are handled in the subsequent *SUB* calls.

PUSHBLOCK arguments are the type and stack, the *POPBLOCK* return value *newpm* is the *cx->blk_oldpm*, which was *PL_curpm* at entry. *PUSHBLOCK* increments *cxstack_ix*, *POPBLOCK* does decrement it.

The *PUSHSUB/POPSUB* pair handles the *cx->blk_sub* record from the very same *cxstack*, the *POPSUB* return value *sv* is the *blk_sub.cv* which was the *cv* from *PUSHSUB*. *POPSUB* also releases *@_*, the *blk_sub.argarray*.

eval

An `eval` call is similar to a `sub` call. The `evaltry` and `eval` op for `eval{}` and `eval ""` just pack the op sequence into a simple try/catch switch between `JMPENV_PUSH` and `JMPENV_POP` calls.

The **struct jmpenv** packages the state required to perform a proper non-local jump, **top_env** being the initial `JMPENV` record. In case of abnormal exceptions (i.e. `die`) a `JMPENV_JUMP` must be done, a non-local jump out to the previous `JMPENV` level with a proper `setjmp` record.
